

§Waves

A periodic wave in space characterized by the distance two corresponding values of the function and is called the wavelength λ . The speed of a wave is

$$v = f\lambda.$$

Any function of the form $f(x - vt)$ with finite support describes a traveling wave in space and time with the forms

$$y_{\text{pos-dir}} = A_+ \cos(k_+x - \omega_+t + \phi_+)$$

$$y_{\text{neg-dir}} = A_- \cos(k_-x + \omega_-t + \phi_-).$$

The angular wavenumber k is defined as

$$k \equiv 2\pi/\lambda$$

which yields another relation for wave speed

$$\omega = kv.$$

Traveling waves can move in both positive and negative directions through time.

$$y_{j+} = A_{j+} \cos(k_{j+}x - \omega_{j+}t + \phi_{j+})$$

$$y_{j-} = A_{j-} \cos(k_{j-}x + \omega_{j-}t + \phi_{j-})$$

In general, waves add at each point in space and time

$$y(x, t) = \sum_{j=1}^N A_{j+} \cos(k_{j+}x - \omega_{j+}t + \phi_{j+})$$

$$+ \sum_{j=1}^N A_{j-} \cos(k_{j-}x + \omega_{j-}t + \phi_{j-}).$$

When waves add interference occurs. For two identical waves save the phase difference

$$y(x, t) = 2A \cos(kx - \omega t + \tfrac{1}{2}\phi) \cos(\tfrac{1}{2}\phi)$$

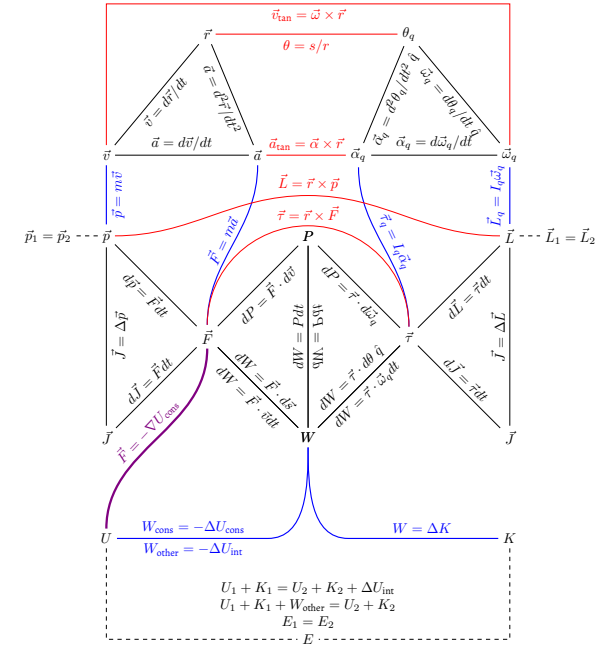

leading to the notions of completely constructive, destructive, and simply reductive interference

$$\phi_{\text{constructive}} = n\pi \quad n = 0, \pm 1, \pm 2, \dots$$

$$\phi_{\text{destructive}} = (2n + 1)\pi \quad n = 0, \pm 1, \pm 2, \dots$$

$$\phi_{\text{reductive}} \neq (\phi_{\text{constr}}, \phi_{\text{destr}})$$

University Physics I - In Brief

§Kinematics

Descriptors of linear motion begin with position \vec{r} and of angular motion with θ_q

$$\vec{v} = d\vec{r}/dt \quad \vec{\omega}_q = d\theta_q/dt$$

$$\vec{a} = d\vec{v}/dt \quad \vec{\alpha}_q = d\vec{\omega}_q/dt.$$

For constant acceleration

$$q = q_0 + v_{q0}t + \tfrac{1}{2}a_qt^2 \quad \theta_q = \theta_{q0} + \omega_{q0}t + \tfrac{1}{2}\alpha_qt^2$$

$$v_q = v_{q0} + a_qt \quad \omega_q = \omega_{q0} + \alpha_qt$$

$$v_q^2 = v_{q0}^2 + 2a_q(q - q_0) \quad \omega_q^2 = \omega_{q0}^2 + 2\alpha_q(\theta_q - \theta_{q0})$$

$$\Delta q = \tfrac{1}{2}(v_{q0} + v_q)t \quad \Delta \theta_q = \tfrac{1}{2}(\omega_{q0} + \omega_q)t.$$

Momentum, impulse, Newton's first law, and Newton's second law are

$$\vec{p} = m\vec{v} \quad \vec{L} = I\vec{\omega}$$

$$\vec{J} = \Delta\vec{p} \quad \vec{J} = \Delta\vec{L}$$

$$\vec{F} = d\vec{p}/dt \quad \vec{\tau} = d\vec{L}/dt$$

$$\sum \vec{F} = m\vec{a} \quad \sum \vec{\tau} = I\vec{\alpha}.$$

Symmetry of physical laws with respect to translation and rotation begets conservation of momentum

$$\vec{p}_1 = \vec{p}_2 \quad \vec{L}_1 = \vec{L}_2.$$

Connections between linear and angular kinematics start with the definition of an angle as the ratio of arc length s to radius r

$$\theta = s/r$$

$$\vec{v}_{\text{tan}} = \vec{\omega} \times \vec{r} \quad \vec{L} = \vec{r} \times \vec{p}$$

$$\vec{a}_{\text{tan}} = \vec{\alpha} \times \vec{r} \quad \vec{\tau} = \vec{r} \times \vec{F}$$

Moment of inertia I is a measure of the resistance of a body to change its rotational motion and depends on the distribution of mass *about a particular axis*

$$I_{\text{discrete}} = \sum_j r_j^2 m_j$$

$$I_{\text{continuous}} = \int r^2 dm$$

About a *parallel* axis the moment of inertia is related to the distance d from the center of mass

$$I = I_{\text{cm}} + Md^2$$

§Work and Energy

Work is the result of a motive cause acting over a path

$$dW = \vec{F} \cdot d\vec{s} \quad dW = \vec{\tau} \cdot d\theta \hat{q}$$

$$dW = \vec{F} \cdot \vec{v} dt \quad dW = \vec{\tau} \cdot \vec{\omega} dt.$$

Kinetic energy expressions for translational and rotational motion are

$$K = \frac{1}{2}mv^2 \quad K = \frac{1}{2}I\omega^2.$$

Two conservative potential energies of interest are gravitational and elastic

$$U_{\text{grav}} = mgh$$

$$U_{\text{el}} = \frac{1}{2}kx^2.$$

Conservative potentials yield forces via the spatial gradient (derivative)

$$\vec{F} = -\nabla U_{\text{cons}}.$$

Symmetry of physical laws with respect to time begets conservation of energy

$$E_1 = E_2.$$

Conservation of energy can be written to highlight the work done or the internal energy change

$$U_1 + K_1 + W_{\text{other}} = U_2 + K_2$$

$$U_1 + K_1 = U_2 + K_2 + \Delta U_{\text{int}}.$$

The work-energy theorem always relates how much work is required to change the kinetic energy

$$W = \Delta K.$$

§Periodic Motion

A periodic wave in time is characterized by the time to complete one cycle called the period T , then linear and angular frequencies obtain

$$f = 1/T \quad \omega = 2\pi f = 2\pi/T$$

A restoring cause that is proportional to displacement

$$F = -kx \quad \tau = \kappa\theta$$

will yield simple harmonic motion with a solution

$$x = A \cos(\omega t + \phi) \quad \theta = A_\theta \cos(\omega t + \phi)$$

$$\omega = \sqrt{k/m} \quad \omega = \sqrt{\kappa/I}.$$

Pendulums with small amplitudes approximate simple harmonic motion

$$k = mg/\ell \quad \kappa = mg\ell$$

$$\omega = \sqrt{g/\ell} \quad \omega = \sqrt{mg\ell/I}$$
